

Today: unitary representations.

Remark So far everything was algebraic, we used only operations  $+$ ,  $-$ ,  $\cdot$ , division by  $|\Gamma|$ .

Jordan decomposition (field is algebraically closed)  $\Rightarrow$  many statements are still true, for instance over

$\overline{\mathbb{Z}/p\mathbb{Z}}$  & algebraic closure if  $p \nmid |\Gamma|$ .

note: in this field we don't have the notion of  $> 0$ .

Over  $\mathbb{C}$  we have complex conjugation, we have  $\mathbb{R} \subset \mathbb{C}$ , on  $\mathbb{R}$  we have  $>$  (order).

Recall: Let  $V$  be a  $\mathbb{C}$ -vector space. A hermitian form on  $V$  is an operation  $(\cdot, \cdot):$

$V \times V \rightarrow \mathbb{C}$ , satisfying

$$(\alpha x, y) = \alpha(x, y) \quad x, y, z \in V$$

$$(x+y, z) = (x, z) + (y, z) \quad \alpha \in \mathbb{C}$$

$$\overline{(x, y)} = (y, x).$$

complex conjugation.

In particular  $(x, x)$  is in  $\mathbb{R}$ .

$\forall x \in V$ .

the form is called positive definite if  $(x, x) \geq 0 \quad \forall x \in V$

and  $(x, x) = 0 \Leftrightarrow x = 0$ .

We say  $\sqrt{(x, x)}$  is the length of  $x$ .

Example:  $V = \mathbb{C}^n$ ,

$$(x, y) = \sum_{i=1}^n x_i \overline{y_i} = \overline{y^t} x$$

$$\underbrace{\begin{pmatrix} \overline{y_1} \\ \overline{y_2} \\ \vdots \\ \overline{y_n} \end{pmatrix}}_{\text{hermitean}} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} = (x, y)$$

Arbitrary form can be written as

$$\overline{y^t} A x \quad \text{for a matrix } A \text{ s.t.}$$

$$\overline{A^t} = A \quad (\text{notation: } A^* = \overline{A^t})$$

$$A^* = A.$$

note: viewing  $\mathbb{C}^n$  as  $\mathbb{R}^{2n}$ , we get the same distance, since

$$x_i = a_i + b_i \sqrt{-1}$$

$$(x, x) = \sum_{i=1}^n x_i \overline{x_i} = \sum_{i=1}^n a_i^2 + b_i^2.$$

Remark if  $V$  is a real vector space with euclidean form,

then there is a corresponding complex vector space  $(V \otimes_{\mathbb{R}} \mathbb{C})$

whose elements are formal combinations

$$V^{(1)} + \sqrt{-1} V^{(2)} \quad \text{for } V^{(1)}, V^{(2)} \in V$$

euclidean form on  $V$  induces a hermitean form on  $V \otimes_{\mathbb{R}} \mathbb{C}$ .

defined in a straightforward way.

( $A$  is a matrix of a euclidean form  $\Rightarrow A^t = A \quad \overline{A} = A \Rightarrow A^* = A$ )

Suppose  $V$  has a hermitean form

Def:  $U: V \rightarrow V$  is unitary if

$$(Ux, Ux) = (x, x).$$

a representation  $(V, \rho_V)$  is unitary if  $\forall g \in \Gamma \quad \rho_V(g)$  is unitary.

Def  $(V, \rho_V)$  is a representation,

is called unitarizable if  $\exists$

a positive definite hermitean form on  $V$  for which it is unitary.

Theorem 1 Every finite dimensional rep of a finite group is unitarizable

Theorem 2 In the case of irreducible representation in a unique way. (up to a scalar multiple)

Pf

1) Let  $(\cdot, \cdot)'$  be some positive definite hermitean form.

$$\text{Let } (x, y) = \sum_{g \in \Gamma} (\rho_V(g)x, \rho_V(g)y)'$$

Clearly  $x \neq 0 \Rightarrow (x, x) = \sum \text{positive terms} > 0$ .

$(V, \rho_V)$  is now unitary.

2) Suppose we have 2 different forms.  $(\cdot, \cdot)_1, (\cdot, \cdot)_2$

$\exists$  a matrix  $A: V \rightarrow V$  s.t.

$$(x, y)_2 = (Ax, y)_1.$$

Claim:  $A \rho_V(g) = \rho_V(g) A \quad \forall g \in \Gamma$ .

Pf:  $(A \rho_V(g)x, y)_1 = (\rho_V(g)x, y)_1$

$$\parallel \quad (x, \rho_V(g)^{-1}y)_2$$

$$\parallel \quad (\rho_V(g)Ax, y)_1 = (Ax, \rho_V(g)y)_1$$

holds for all  $y \Rightarrow A \rho_V(g)x = \rho_V(g)Ax$

holds for all  $x \Rightarrow A \rho_V(g) = \rho_V(g)A$ .

By Schur's lemma  $\exists \lambda \in \mathbb{C}$  s.t.

$$A = \lambda I. \text{ Hence}$$

$$(x, y)_2 = \lambda (x, y)_1 \Rightarrow \lambda \text{ a positive real number.}$$

we had  $\chi(g^{-1})$  in orthogonality relation for instance

$$\frac{1}{|\Gamma|} \sum_{g \in \Gamma} \chi_{V_1}(g) \chi_{V_2}(g^{-1}) = \begin{cases} 0 & V_1 \neq V_2 \\ 1 & V_1 = V_2 \end{cases}$$

Observation for any representation  $(V, \rho_V)$   $\chi_V(g^{-1}) = \overline{\chi_V(g)}$ .

Pf 1  $\rho_V(g)$  can be diagonalized,

so that on the diagonal we have roots of unity  $e^{2\pi i \frac{k}{|\Gamma|}}$   $k \in \mathbb{Z}$

$\Rightarrow \rho_V(g^{-1})$  will have eigenvalue  $e^{2\pi i (-\frac{k}{|\Gamma|})}$  where  $\rho_V(g)$  had  $e^{2\pi i \frac{k}{|\Gamma|}}$ ,

$$\text{also } e^{2\pi i (-\frac{k}{|\Gamma|})} = \overline{e^{2\pi i \frac{k}{|\Gamma|}}} \Rightarrow$$

$$\text{the sum, } \chi_V(g^{-1}) = \overline{\chi_V(g)}.$$

Conclusion:

$$\frac{1}{|\Gamma|} \sum_{g \in \Gamma} \chi_{V_1}(g) \chi_{V_2}(g) = \begin{cases} 0 & \dots \\ 1 & \dots \end{cases}$$

so characters are orthogonal with respect to the standard hermitean form.

Def Element  $g \in \Gamma$  is called real if  $g$  is conjugate to  $g^{-1}$ .

Prop  $g$  is real if and only if for all irreducible characters  $\chi$

$$\chi(g) \in \mathbb{R}.$$

Pf  $g, g^{-1}$  are in the same conjugacy class  $\Leftrightarrow$

$$\chi(g) = \chi(g^{-1}) \text{ for all } \chi.$$

$$\Leftrightarrow \chi(g) = \overline{\chi(g)}.$$

Example in  $S_n$ , quaternions  $D_4$ ,

all elements were real.

So character tables are real.

in  $\mathbb{Z}/m\mathbb{Z}$  ( $m \geq 3$ ), Heis  $p$  ( $p \neq 2$ )

not all elements are real.

Another proof of  $\chi(g^{-1}) = \overline{\chi(g)}$

unitary matrix  $U$  satisfies

$$U^* U = I \Rightarrow U^{-1} = U^*$$

$$\text{tr}(U^{-1}) = \text{tr}(U^*) = \overline{\text{tr}(U)}$$

$$\parallel \text{tr}(U) = \overline{\text{tr}(U^{-1})}$$

$$\text{tr}(U) = \overline{\text{tr}(U^{-1})}$$

$$\text{tr}(U) = \overline{\text{tr}(U^{-1})}$$

# Compact groups

Def A compact group  $\Gamma$  is a topological space and a group such that multiplication  $\Gamma \times \Gamma \rightarrow \Gamma$ , inverse  $\Gamma \rightarrow \Gamma$  are continuous and  $\Gamma$  is compact.

Examples Recall  $X \subset \mathbb{R}^n$  is compact if  $X = \bar{X}$  (closed) and bounded.

By imposing equations on matrix groups we can construct many examples.

x)  $GL_n(\mathbb{R}) \subset \mathbb{R}^{n^2}$  not closed  $\Rightarrow$  not compact.

$SO_n(\mathbb{R})$  is compact

$$x) SO_n(\mathbb{R}) = \left\{ g \in GL_n(\mathbb{R}) \mid g^t g = I, \det g = 1 \right\}$$

Since  $SO_n(\mathbb{R}) \subset \mathbb{R}^{n^2}$  is given by continuous equations, it is closed,  $g = (v_1, \dots, v_n) \in SO_n(\mathbb{R})$ ,  $v_i \in \mathbb{R}^n$

$$\|v_i\| = 1 \Rightarrow |g|^2 = n \Rightarrow SO_n(\mathbb{R}) \text{ is bounded.}$$

$$1) O_n(\mathbb{R}) = \left\{ g \in GL_n(\mathbb{R}) \mid g^t g = I \right\}$$

$$2) SL_n(\mathbb{R}) = \left\{ g \mid \det g = 1 \right\}$$

$$3) Sp_{2n}(\mathbb{R}) : \mathcal{Y} = \begin{pmatrix} 0 & I_n \\ -I_n & 0 \end{pmatrix}$$

$$Sp_{2n}(\mathbb{R}) = \left\{ g \mid g \mathcal{Y} g^t = \mathcal{Y} \right\}$$

$$4) GL_n(\mathbb{C}) = \left\{ g \in \mathbb{C}^{n \times n} \mid \det g \neq 0 \right\}$$

$$5) U_n(\mathbb{C}) = \left\{ g \in GL_n(\mathbb{C}) \mid g^* g = I_n \right\}$$

$$6) SU_n(\mathbb{C}) = \left\{ g \in U_n(\mathbb{C}) \mid \det g = 1 \right\}$$

$$7) SO(m, n, \mathbb{R}) \quad m > 0 \quad n > 0$$

$$A = \begin{pmatrix} \underbrace{1 \dots 1}_m & & & 0 \\ & \underbrace{-1 \dots -1}_n & & \\ & & & \\ 0 & & & \end{pmatrix} \left\{ \begin{array}{l} g \in GL_n(\mathbb{R}) \\ g A g^t = A \\ \det g = 1 \end{array} \right\}$$

Which are compact?

Answers in chat. (11:02)

$$SL_2 \ni \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \quad x \rightarrow \infty$$

$Sp_{2n}(\mathbb{R})$  symplectic group.

$$g = \begin{pmatrix} I & \lambda \cdot I \\ 0 & I \end{pmatrix} \in Sp_{2n} \quad g \mathcal{Y} g^t = \begin{pmatrix} 1 & \lambda \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \lambda & 1 \end{pmatrix}$$

$$n=1: Sp_2(\mathbb{R}) = SL_2(\mathbb{R}) \quad \begin{pmatrix} -\lambda & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \lambda & 1 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

$SO(1,1)$  columns satisfy

$$\begin{pmatrix} x \\ y \end{pmatrix} \quad x^2 - y^2 = 1 \leftarrow \text{unbounded}$$

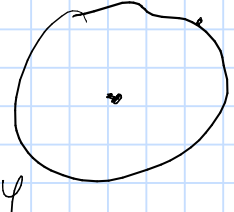

$$\text{instead of } x^2 + y^2 = 1 \rightarrow \text{bounded}$$

$$SO(2) = \left\{ \begin{pmatrix} \cos \varphi & \sin \varphi \\ -\sin \varphi & \cos \varphi \end{pmatrix} \right\}$$

$$SO(1,1) = \left\{ \begin{pmatrix} \cosh \varphi & \sinh \varphi \\ -\sinh \varphi & \cosh \varphi \end{pmatrix} \right\}$$

From representation theory point of view many tricks that worked for finite groups also work for compact groups (for continuous representations) replacing  $\sum_{g \in \Gamma}$

by  $\int_{g \in \Gamma} \dots \mu(dg)$  so-called Haar measure.

Ex  $U(1) \approx$  

$$\begin{array}{c} \text{---} \\ 0 \quad \varphi \quad 1 \end{array}$$

Usual reason  $\perp$  Fourier analysis.
